Linux based 3G Specification

Multimedia Mobile Phone API

Preface

Document: CELF_MPP_Preface_FR2_20060606

WARNING : This is a working draft for review only, it is NOT a published specification of the CE Linux Forum. It is likely that further substantial changes will be made in the course of review and issue resolution. Send comments on this version to:

MppApiComments@tree.celinuxforum.org

60 0. Introduction

61 This Preface to the CELF Mobile Phone API describes the overall structure of the API specification of the
62 Telephony Service for 3G multimedia mobile telephone based on Linux. It also provides an introduction to
63 some common concepts and terminology used in the Specifications and defines some common datatypes.

64 This document is the work of the CE Linux Forum's Mobile Phone Profile Working Group [MPPWG].

65 The major sections of the API in the current release are described below. This Preface and the individual
66 Service chapters are considered normative; a conforming implementation is required to satisfy statements
67 written in "SHALL" form. However, conformance may be determined on a service-by-service basis.

68 0.1.1 Circuit Switched Communication Service

69 The Circuit Switched Communication Service (CS Service) API [CS] provides access to functionality for
70 call control, call state management, tone control, and log processing. This chapter includes the Voice
71 communication service, the Video communication service, and the Unrestricted Digital data
72 Communication service.

73 0.1.2 Packet Switched Communication Service

74 The Packet Switched Communication Service (PS Service) API [PS] provides access to functionality for
75 packet call control and for sending and receiving data packets. This chapter includes the PPP dial-up
76 communication service and the IP connection data transfer service.

77 0.1.3 Reference Architecture

78 The Reference Architecture [RefArch] is an illustrative, non-normative description of a commonly
79 understood way of implementing mobile handsets using a Linux-based application environment. A
80 conforming implementation is not required to conform to the reference architecture.

81 0.2 Structure of API Documents

82 Each specification chapter defines the API for a major sub-area of functionality. The content of each
83 chapter is divided into:

- 84 1. Introduction – An overview of the service, placing it in context.
- 85 2. Primitives – Definitions of the data types, constants, and enumerations used in the API definitions.
- 86 3. Functions – Definitions of the individual functional interfaces provided by the service.

87 0.2.1 Introduction Section

88 An introduction to the functionality available through the API of the service described by the chapter.

89 0.2.2 Primitives Section

90 This section is subdivided into sub-sections for Data Types and Structures and for Constants. In each case,
91 the primitive is named, its use is described, and its formal definition (as would appear in a header file) is
92 given.

93 0.2.3 Functions Section

94 Each function appears as a separate section. The information given for each function includes:

95 Symbol	The formal (programming) name of the function.
96 Syntax	Syntax used in programming in C language
97 Argument	Arguments of API function in C language
98 Return value	Return value of API function in C language

- 99 Include file File name to be included in Programming
- 100 Functional description Definition and detail explanation of API function

101 0.3 Terminology and abbreviations

102 The following words, phrases, and acronyms have specific meanings within the context of the API.

word	explanation
32K AV communication	Communication mode with AV at the speed of 32Kbps
32K data communication	Data communication mode at a stable communication speed of 32Kbps. Unlimited digital 32K communication.
64K AV communication	Communication mode with AV at the speed of 64Kbps
64K data communication	Data communication mode at a stable communication speed of 64Kbps. Unlimited digital 64K communication.
accumulated reset	Resetting of the accumulated duration data. The handset stores data on the total duration of all calls .
API	Application Program Interface
APN	Access Point Name
App or Application	Application program; a program run in user space.
ASF	Advanced Streaming Format
automatic incoming call	Operating mode in which the handset automatically accepts incoming calls, without the user accepting each call by a manual operation..
automatic transmission	Placing a call by keying in all the digits and then initiating the connection. Same as “on-hook originating”.
call duration	The duration of a voice call.
call quality alarm	The indication that radio reception from the network has deteriorated and the call is likely to be dropped.
call reference	An identifier for a particular call. This identifier is assigned by the network or mobile phone, and used in the call-management APIs to operate on a particular.
C Plane	Control Plane – the subset of components in a network architecture that are responsible for controlling connections.
CS	Circuit Switched operation; a mode of communication in which a dedicated channel is maintained between the handset and the remote party and the call content is routed over that identified channel.

Classification: Mobile Phone API

DCF	Device Control Function. The module that provides the following functions: <ul style="list-style-type: none"> • Mobile phone control via AT commands. • Monitoring S-IF message and notice status change event to service. • To notice MTF (block which exchange message between TAF-NW) when sets up receive denial.
DTMF	Dual Tone Multi Frequency. The tones generated to correspond to key presses while a CS connection is open (off-hook originating). On digital connections, the tones may be represented by designated codes rather than encoded audio.
Earphone (external option)	Controls whether audio is routed to an attached earphone (headset) or to a built-in loudspeaker.
emergency originating restriction	A network condition in which call from handsets are not accepted because an emergency requires all of the available network capacity..
Engine	Application Engine; a software module providing “backend” processing to support a service interface.
external AV communication	Videophone communication using a USB connection cable, etc., to connect terminal and external equipment (such as a PCⓂpersonal computer) to the handset).
FLASH	Macromedia Flash Player; the engine that execute Flash programs.
H234 and H324M	3G multimedia services – H324M is video telephony, H234 is encryption key management
high priority communication mode	The display mode in which an alert or icon is displayed in case of <ul style="list-style-type: none"> (a) an incoming packet switched communication when circuit switched communication is active, or (b) an incoming circuit switched communication when packet switched communication is active.
hold tone	A tone or melody that sounds when a voice call or AV call is changed to hold status.
HTTP	Hyper Text Transfer Protocol
I/F	Interface
IMEI	IMEI (International Mobile Station Equipment Identity). A unique number allocated to each individual mobile station (handset).
internal AV communication	Videophone communication between terminals.

IR	Infra-Red
JAM	Java Application Manager
JVM	Java Virtual Machine
Kernel	Linux Kernel
keypad dial lock	When this function is set, the handset does not allow voice or videophone calls by dialing phone numbers, extension number, or SIP. Dialing from previously stored "Phonebook" entries and from the "Dialed calls" or "Redial" entries remains possible.
LCD	Liquid Crystal Display
Low-voltage alarm	The alarm sounded to indicate that the battery is about to run out of power.
manner mode	Manner mode provides a quick and convenient way of muting the terminal's ring tones and keypad sound to avoid disturbing people around you.
manual transmission	Same as off-hook originating
MAW	Monitoring and Watching
MPPWG	The CE Linux Forum's Mobile Phone Profile Working Group, which defined this specification and the related Service specifications.
MSB	Mobile Software Bus
multiple calls	It is the combination of maximum three call. The conversation, hold and incoming call is at most one call.
noise canceller	A function that reduce ambient transmitted over a connection so that the other party can hear the voice more clearly.
normal originating restriction	When this mode is set, outgoing calls are permitted only to designated special numbers.
number notification	On option that determines whether the handset's telephone number is sent to the other party when a call is initiated.
OBEX	Object Exchange protocol
OCR	Optical Character Recognition
off-hook originating	Placing a call by keying the digits after pressing the start button; when five seconds have elapsed since the last input digit the call is initiated.
on-hook originating	Placing a call by pressing the start button after inputting all dial digits.
out-of-communication area	The mode of operation when the handset is unable to establish communication with the network because it is out of the service area or the signal is too weak or there is no network with which the handset is

	allowed to register.
phone-answering message	A message sent to the calling party when the handset can not respond to an incoming call.
phone-answering message service	A network-side service that provides for recording messages from callers when the handset is not in service..
PIM lock	A handset mode in which the user has indicated that no access is allowed to personal-information resources, such as "Phonebook", "Schedule", "Mail", "Messenger", and "Presence".
PIN	Personal Identification Number
PS	Packet Switched network
receive level	The receive level is the strength of the radio signal received from the network.
reconnection tone	The tone that sounds when the handset reconnects to the network after being out of service.
SCA	Stream Control API
SD	SD memory card
SDFS	SD File System
secret mode	A handset mode that controls whether personal information resource display or hide those entries that have been marked by the user as secret.
SMS	Short Message Service
special number	A number to connect with a service center in the network.
SS	A Supplementary network service accessible using the SS protocol, which encodes a service code as a four-part data string starting with '*', '#', or '*#' and ending with '#'. The service code is either a standardized 3GPP code or a code defined by operator (USSD).
SSL	Secure Socket Layer
supplementary service	An optional service provided by the network and available to the handset through special signalling.
TAF	Terminal Adaptation Function. The module that connects handset functions to communication services.
U Plane	User Plane – the subset of components within a network architecture that are responsible for the transfer of user data.

UIM	Same as USIM (Universal Subscriber Identity Module).The removable hardware module that contains information identifying a network account plus various kinds of user-defined information (phone book entries, messages, service-specific information, applications, etc.).
USSD	Unstructured Supplementary Service Data a network- specific supplementary service code.
WDC	Watching Device Condition
within-communication area	The condition when the handset is in service area and able to communicate with the network.

112 [MPPWG]

113 1. Programming Model

114 The MPP API defines both synchronous and asynchronous interfaces. Synchronous interfaces return a
115 result directly to the calling program, whose execution is blocked until the function returns. Asynchronous
116 interfaces return a result directly, but the result indicates only whether the request was successfully
117 initiated. The actual result of an asynchronous service request is received as an event notification sometime
118 after the request has been made. Asynchronous operations are used when the delay involved in processing a
119 request is likely to be long for the client to block and be unable to do other work.

120 1.1 Events and Notifications

121 MPP API clients can register with service providers to receive notification when specified events occur.
122 The API implementation delivers notifications by calling a function (the **callback** function) specified by the
123 client at the time the client registered the request for notification. Registration is persistent; a client remains
124 registered until it explicitly unregisters or exits.

125 The event-delivery model is widely used throughout the interface, both for delivering the results of
126 asynchronous service requests (“result events”) and for notifying clients of events that occur in the system
127 (“spontaneous events”). For instance, a client can register to receive notification when an incoming call
128 arrives from the network.

129 1.1.1 Spontaneous Events

130 Spontaneous events are the means by which clients become aware of activities of the network or of
131 anomalous situations in the device (such as **low battery conditions**). Spontaneous-event notifications are
132 multicast: when a spontaneous event occurs, the server implementation calls the notification callback
133 functions of all clients that have registered for notification of the given event. While multiple clients may
134 register for notification of a given event, each may register only one callback for that event – each
135 registration replaces any previous registration by that client.

136 1.1.2 Result Events

137 Result events are the means by which clients receive the results of asynchronous operations. When the
138 server completes processing of an asynchronous service request, it calls the notification callback function
139 most recently registered for that event by the client. The client may register only one callback for a given
140 result; each registration replaces any previous registration. Result Events are delivered only to the
141 application that requested the service.

142 1.1.3 Application IDs

143 In order for events to be delivered to the right client, each client provides an application ID to the server
144 when it registers for notifications. The ID is a unique integer value associated with each application or
145 server that needs to receive events. No special semantics are associated with the value, but it must be
146 unique for each client.

147 1.1.4 Callback Notification Functions

148 When an event occurs, the service implementation calls the callback notification function(s) registered for
149 that event. The function is called with one argument, a pointer to a `CelfMpEvent` structure, which contains
150 a fixed part with members that identify the type and subtype of the event and an open part that contains
151 data fields appropriate to the specific event type.

152 The function is called in the process context of the client, so the client’s internal namespace is available in
153 writing the function. The method by which the system arranges for the process to be called in the client’s
154 context is outside the scope of the API definition.

155 1.1.5 Registering

156 A client requests notification of particular events by calling a registration function (which usually has a
157 name that starts with “start” and ends with “notification”), providing a application ID, event mask, and call
158 back function pointer as arguments. The event mask indicates which of the events provided by the
159 particular service the client is requesting notification for. There is a separate notification_..._start() function
160 for each cluster of services in the MPP API; for instance, the SMS service has a registration service
161 separate from the packet-switched communications service.

162 1.2 Synchronous Service Interfaces

163 The processing of a synchronous request looks to the client like any other normal function call. The
164 implementation may do special processing to pass associated data between the client’s process context and
165 the service implementation’s process context, but that is outside the definition of the API. The client
166 process is blocked during the processing of the request and resumes execution with the assignment of the
167 provided result into the given variable (if appropriate).

168 1.3 Asynchronous Service Interfaces

169 To use an asynchronous service, the client must first call an interface to register to receive the notifications
170 associated with the service to be requested. The registration request would include a list of the events
171 requested and the callback function the server should call when the given events occur. A client may
172 register different callbacks for different events provided by the same service.

173 When the client makes an asynchronous request, it receives a result from that function call that indicates
174 whether the server accepted the request successfully. The client can then continue doing whatever
175 processing it has to do or can block waiting for the result to come back through a call to one of the callback
176 notification functions that it has registered.

177 When an event occurs (either completion of a service request or a spontaneous event), the MPP server will
178 check to see whether any clients are registered for that event and, if so, will arrange for the callback
179 notification functions that those clients registered against the event to be called in the application process
180 context.

181 2. Common Primitives

182 This section documents data types and values used throughout the sections of the API specification.

183 2.1 Constants

184

185 2.2 Enums

186 2.2.1 CelfMpStatus

187 **Description:** Status returned by MPP API functions

188

189 **Definition:**

190 CELF_MP_STATUS_OK: Successful completion

191 CELF_MP_STATUS_APP_ID_ERR: Invalid Application ID

192 CELF_MP_STATUS_EVENT_SET_ERR: The set of event is invalid

193 CELF_MP_STATUS_CALL_REF_ERR: Invalid Call reference

194

195 CELF_MP_STATUS_PS_PDP_TYPE_ERR: Unsupported PDP type

196 CELF_MP_STATUS_PS_DENIED: Request rejected by network due to no
197 subscription to packet communication service

198

199 CELF_MP_STATUS_ERR: Other error

200

201

202 2.3 Data Types and Structures

203 2.3.1 CelfMpCallRef

204 **Description:** Call Reference for the current call. Service requests that establish calls return
205 the Call Reference identifying that call.

206

207 **Definition:** `typedef unsigned char CelfMpCallRef;`

208

209 2.3.2 CelfMpEvent

210 **Description:** MPP notification events structure

211

212 **Definition:**

213

```
214 typedef struct {
215     int    category ;
216     int    subtype ;
217     int    info ;
218     int    subinfo ;
219     union {
```

```
220         ...
221         messages structures
222         ...
223     } data ;
224 } CelfMpEvent;
225
```

2.3.3 CelfMpCallback

Description: Pointer to a callback function

Definition: `typedef void (* CelfMpCallback)();`

2.3.4 CelfMpAppId

Description: Application ID

Definition: `typedef int CelfMpAppId;`
