DRAFT

73 0. Introduction

74 This document defines a Reference Architecture – a commonly-understood organization of
75 components for implementing mobile handsets. The purpose of a reference architecture is to
76 define a standard vocabulary for talking about products in a domain. A practitioner should
77 recognize the components and the organization of the components of typical handsets as
78 variations on such a reference architecture. The purpose of this Reference Architecture is
79 explanatory rather than constraining. Typical products will have implementation architectures that
80 modify or extend this architecture in various ways.

81 Chapter 1 is an overview of the domain, characterizing different product tiers.

82 The basic architecture is described in chapter 2

83 The functions of each component of the architecture are described in chapter 3.

84 The data and control flows between components during typical use cases are described in
85 chapter 4.

86 0.1 Scope

87 This document defines the reference architecture of Linux-based mobile phone. This is a non-
88 normative part of the Specification. The goal of the Reference Architecture is to provide the
89 context for the descriptions in the normative parts of the Specification.

90 The Reference Architecture does not describe the internal architecture of the communication
91 protocol stack or the Application Framework.

92 0.2 Vocabulary and Abbreviations

93 See the corresponding section in the Preface document.

104

1. The Mobile Phone Domain

105

It is customary in the mobile handset industry to describe phones as falling into different “tiers,” broad classes of phones with common characteristics – feature set, price, display size, etc.

106

107

Because different tiers have different performance, price, and feature requirements, they will often be implemented by different software and hardware architectures.

108

109

Table 1 gives working definitions of a set of Reference Tiers. Note that these represent a particular point in time (end-of 2004) and some of the details of specific areas will change as technology changes. Many products do not fit neatly into one niche and will blend characteristics of different tiers. Also, many products will add features not covered by this table.

110

111

112

113

The Reference Architecture corresponds broadly to the “Smart Phone” and “Multimedia Phone” tiers in this table. The differences between those tiers are typically in the application of the architecture (the way it is used) and in the details of the components and the physical characteristics of the device. This architecture could be used for the lower tiers (“Feature Phone” and “Plain-Old Mobile”), but would include capabilities and performance enablers that would probably make such application economically inappropriate. However, as component costs decrease and their performance increases, it might become practical to use this architecture more broadly; the economies of scale resulting from reusable components might offset the hardware costs.

114

115

116

117

118

119

120

121

| | Tier | | | |
|-----------------------|--|--|---|-------------------------|
| Aspect | Smart Phone | Multimedia Phone | Feature Phone | Plain-Old Mobile |
| Focus | business focus | Personal/Entertainment Focus | Lifestyle Focus (voice plus social networking support features) | Voice |
| Primary Functionality | Full PDA functionality (Calendaring, address book) | Strong PIM support, personal content management features | Minimal PIM functionality (phonebook, datebook) | Phonebook and call logs |
| Extensibility | Extensible (downloadable features) | Limited extensibility (MIDlets or BREW) | Limited extensibility (MIDlets/BREW) | No extensibility |
| Multimedia | Optional | Video capture support, Media/content players, stereo | Limited multimedia support (pictures, MP3, MIDI, Simple, low-frame-rate animations) | None |
| DRM | Optional | Multiple DRM schemes | Hard DRM (limits on copying any media of given types) | None |
| Camera | Optional | 2-3 megapixel camera | VGA camera or no camera | No camera |

| | Tier | | | |
|---------------------|--|---|--|--|
| Aspect | Smart Phone | Multimedia Phone | Feature Phone | Plain-Old Mobile |
| Browser | XHTML Browser | XHTML Browser | WAP Browser (text-centric) | Embedded access to specific URLs |
| Display | QVGA or larger color display | QSIF or larger color display | QSIF or smaller color display | Small display (64x96), non-color |
| Interaction | Touchscreen UI or QWERTY keyboard plus pointing device | Specialized keypad for media/game interaction | Standard keypad plus carrier-specific keys | Standard keypad |
| Connectivity | 3G connectivity, possibly WLAN, Bluetooth, IrDA | 2.5G or 3G connectivity, possibly WLAN; High-speed USB; Bluetooth | 2G connectivity; USB or serial cable | 2G connectivity; proprietary accessory cable |
| Memory | 32M RAM, 64M ROM, removable storage | 64M RAM, 64M ROM, Hard Disk or large removable storage | 16M RAM, 16M ROM, no removable storage | 8M RAM, 8M ROM or less |
| Processor | 120MHz | 200MHz | 30MHz | 15MHz |

122

123

2. Architecture

124

This document describes a reference architecture for mobile phones based on the Linux operating system. Any real product would be likely to have an implementation architecture that modifies or extends this reference architecture.

125

126

The architecture separates processing between two domains: the application domain and the communications domain. The two domains might run on separate processors, as separate processes on a single architecture, as separate virtual processors running over a micro-kernel, or other physical implementation. The Communications domain would include all activities requiring hard real-time behaviour.

127

128

129

130

131

Figure 1 is a top-level view of the architecture. Note that while the layering between the large boxes is meant to be strict (for instance, Applications interact with the Kernel only through Middleware components, not directly). The horizontal arrangement is arbitrary.

132

133

134

The Reference Architecture identifies this partitioning of processing domains but does not dictate the physical realization used. In Figure 1, the Bridge represents whatever mechanism is used in the particular realization to support interaction between the domains. The implementation of the Bridge is not in the scope of the Reference Architecture.

135

136

137

138

The blocks shown with a white background in Figure 1 are not part of the scope of the Mobile Phone API. They are shown as part of the common understanding of the structuring of a Linux-based mobile phone.

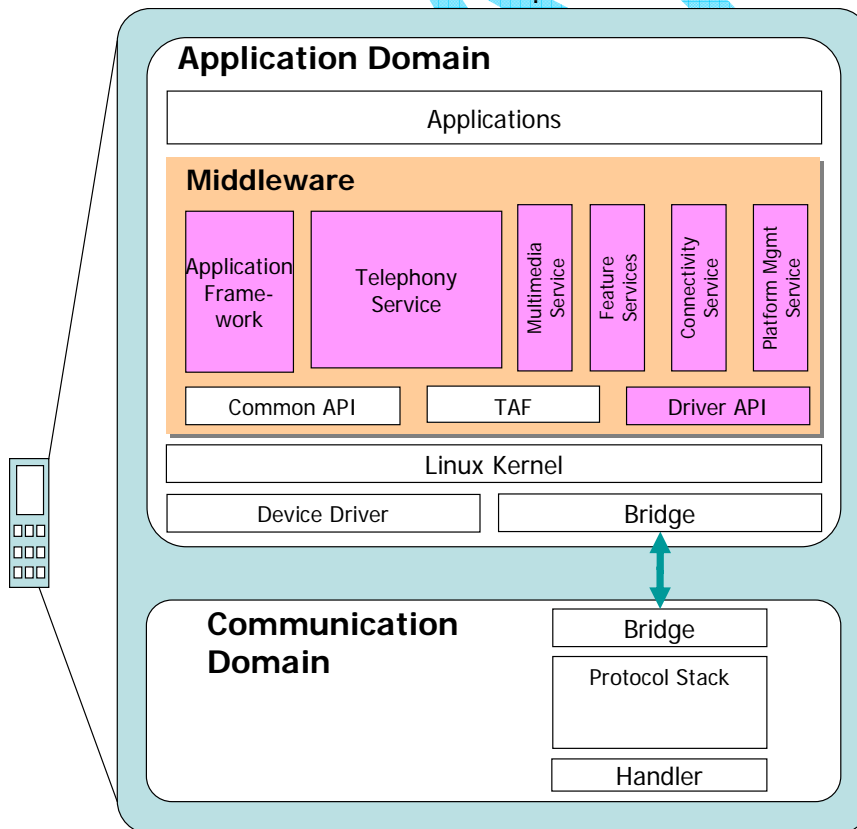

139

140

141

142

143

144

145

Figure 1 Overall Architecture

146 **2.1 Applications Domain**

147 The software running in the Application Domain contains the following 4 layers:

148 Application

149 Middleware

150 Linux Kernel

151 Driver & Bridge

152 **2.1.1 Application Layer**

153 The application layer contains various applications. They are classified into the following 8
154 categories; samples are listed to illustrate the categorization, but are not meant either to be
155 requirements or to be a complete list of the applications in a given category:

156 **2.1.1.1 Telephony Applications**

157 Telephony applications include Standby Screen (Idle), main menu, videophone application,
158 phone applications, phonebook and other Personal Information Management (PIM) applications,
159 and phone personalization settings.

160 **2.1.1.2 System Applications**

161 System applications include Air download, Generic LCD display, Backside LCD display, PIN
162 authentication and monitor mode, other function setup, Equipment alarm, etc.

163 **2.1.1.3 Multimedia Applications**

164 Multimedia applications include still image viewer, video viewer, camera app, vector graphics
165 viewer, avatar and ring tone management.

166 **2.1.1.4 Feature Applications**

167 Data-processing applications include OCR, barcode, SD-PIM, data transfer, memory transfer,
168 external I/F communication, user data, IR, schedule, personal productivity, voice memo, schedule
169 alarm, and data folder.

170 **2.1.1.5 Internet Applications**

171 Internet applications are those that use TCP/IP to access resources on the internet, including e-
172 mail, Browser, HTML mailer, etc.

173 **2.1.1.6 Internet Application Engine**

174 Internet application engines are application-level services that would be used by applications that
175 include internet-enabled functions; examples include engines for HTTP, SSL, embedded
176 languages, etc.

177 **2.1.1.7 Java Application Engine**

178 The Java applications engine includes a Java Virtual Machine (JVM), Java Application Manager
179 (JAM), and class libraries.

180 **2.1.2 Middleware Layer**

181 Middleware layer contains the following components.

182 **2.1.2.1 Applications Framework**

183 The Applications framework provides application developers with a common framework of
184 services commonly used by mobile-phone applications.

185 **2.1.2.2 Telephony Service**

186 The telephony service provides application developers with a framework of services for
187 communications and handset management.

188 **2.1.2.3 Multimedia Service**

189 The multimedia service provides video phone service (H324, for example), and multimedia data
190 decoding, encoding, and rendering facilities.

191 **2.1.2.4 Feature Services**

192 Most phones will have some differentiating features, such as location awareness, that will be
193 exposed as services usable by one or more client applications.

194 **2.1.2.5 Platform Management Service**

195 The Platform Management Service provides the functions of system management, including
196 installation of software and control of system processes.

197 **2.1.2.6 Connectivity Service**

198 The Connectivity Service handles inter-device functions, such as synchronization and OBEX data
199 exchange.

200 **2.1.2.7 TAF (Terminal Adaptation Function)**

201 The TAF provides the back-end services needed by the Telephony Service APIs [TAF]. It
202 mediates between the phone software's model of network programming and the specifics needed
203 for the particular networks supported by a specific handset. Note that the TAF could equally well
204 be located in the Communications Domain or in the device driver layer; the placement shown in
205 the diagram is common, but not universal.

206 **2.1.2.8 Common API**

207 The Common API provides application developers with standard C-language functions, including
208 standard libraries and system calls.

209 **2.1.2.9 Driver API**

210 The device-driver API provides middleware and application programs access to devices and to
211 services modeled as devices.

212 **2.1.3 Kernel/Driver Layer**

213 **2.1.3.1 Kernel and Device Drivers**

214 The Kernel / Driver layer contains the Linux Kernel and device drivers and the Application-
215 Domain end of the Bridge.

216 **2.1.3.2 Bridge**

217 The Bridge supports communication between the Application and Communication domains,
218 which may be implemented as separate processors or not, but will minimally have different
219 scheduling regimes.

220 **2.2 Communications Domain**

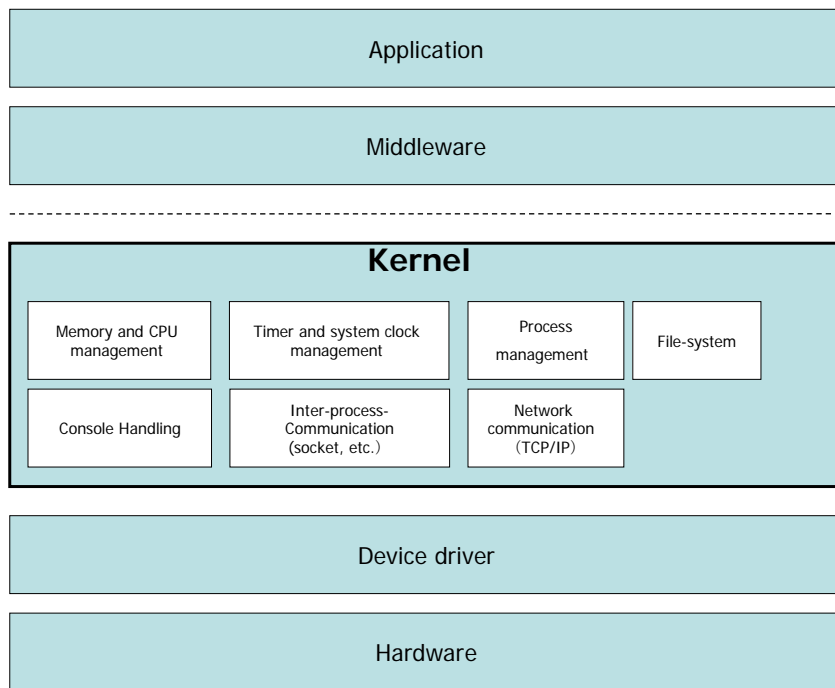

221 The Communications Domain performs all processing that requires hard real-time behaviour,
222 including executing the lower levels of the protocol between the device and the network. Its
223 protocol stack contains the network stack's L1, L2, L3 layers. The Bridge supports communication
224 with the Applications Domain.

225 **3. Description of functional entities**

226 **3.1 Linux Kernel**

227 The Linux Kernel provides:

- 228 • Memory and CPU management
- 229 • Timer and system clock management
- 230 • Process management: create, destroy and dispatch
- 231 • File-systems: files, directories, and space management
- 232 • Console handling
- 233 • Inter-process-communication: sockets, message queues, shared memory, etc.
- 234 • Network communication: TCP/IP

235

236

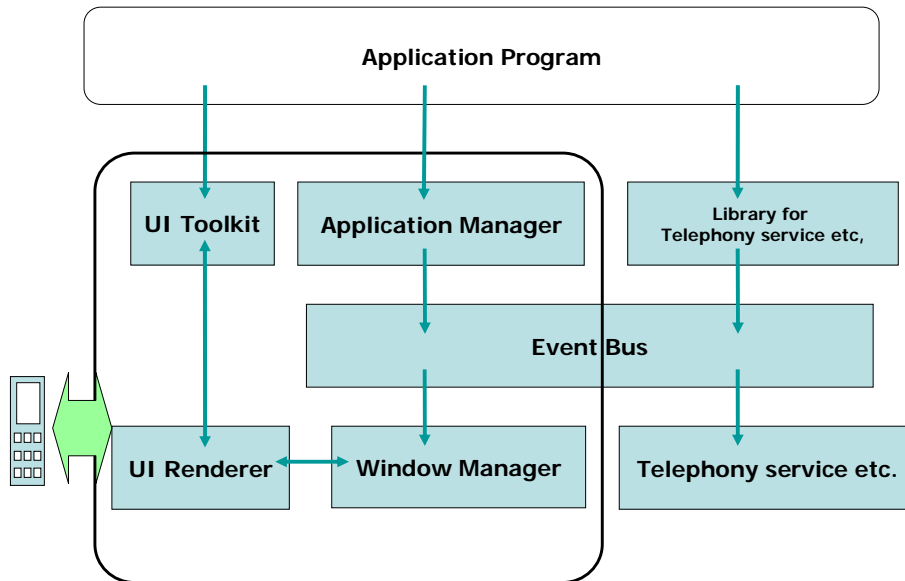

Figure 2 Linux Kernel

237 **3.2 Common API**

238 The Common API contains various functions for applications to use, including the standard C
239 libraries. The Common APIs conform to the POSIX standard.

240 **3.3 Application Framework**

241 Figure 3 is an overview of the application framework. This is an area where variation is common
 242 in the domain, with the specific requirements of the application set and the UI framework chosen
 243 for specific products potentially differing from this reference architecture, Usually, however, the
 244 functional separation is similar to this.

245

246

Figure 3. Application Framework

247 **3.3.1 Window Manager**

248 The Window Manager provides unified operation and decoration for windows and controls
 249 overlap of windows (clipping and layering).

250 In the Application framework for mobile-phone, window manager provides:

251 Foreground and background control of application window

252 Tracking the state of applications (active, inactive, idle, not-started)

253 **3.3.2 Application Manager**

254 The Application Manager (AM) controls the start and end of applications. That is, starts
 255 applications, switches between applications, and shuts down applications at power-off. AM also
 256 manages application start status, and controls application switching operation (e.g., selection of
 257 an application to be next used as a foreground application at application switching).

258 The Window Manager controls window stacking, focusing, and properties for each group during
 259 the period from window generation to deletion. The Window Manager receives requests from the
 260 AM through the Event Bus and resolves contention between applications, according to the priority
 261 table based on the application status. It also control windows overlapping and key focusing.

262 The Application Manager uses the Event Bus to communicate between applications and the
 263 Window Manager.

264 **3.3.3 UI Toolkit**

265 The UI Toolkit is a set of functions and facilities for the application to use to present and manage
266 interaction with the user.

267 **3.3.4 UI Renderer**

268 The UI renderer controls presentation of the interaction elements on the display(s).

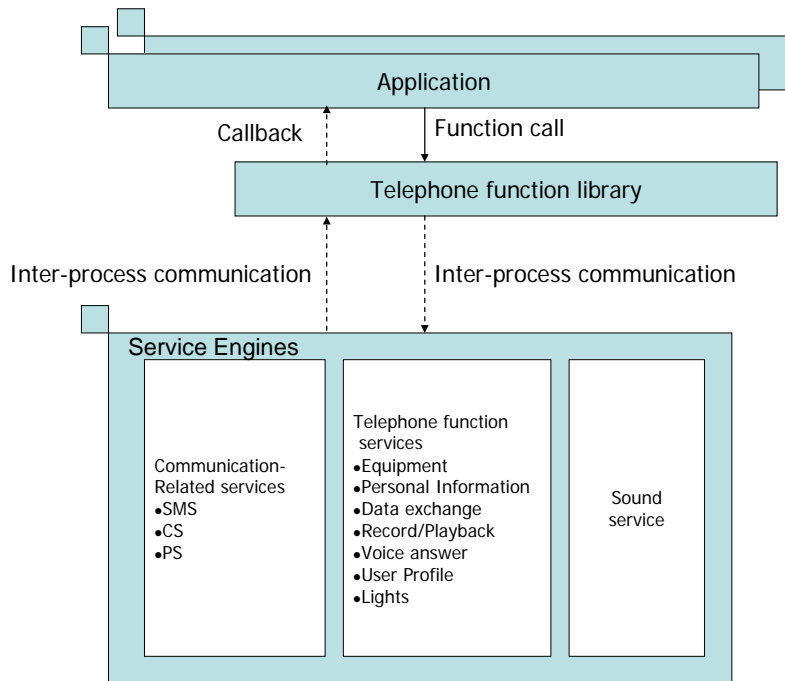

269 **3.3.5 Event Bus**

270 The Event Bus is a framework for passing messages between entities. It supplies communication
271 services (synchronous and asynchronous communication) between applications and services.
272 Different implementations of the reference architecture may use different kinds of inter-process
273 communication for this role. See [Preface] for more information about the programming model
274 and the portion of the Event Bus semantics that are visible in the APIs.

275 **3.4 Telephony Service**

276 Figure 4 describes the telephony processing framework. The Telephony Service provides
277 abstract (not specific to the network technology or the handset hardware) APIs for applications to
278 use to access the functions of the handset, including both communications services and control of
279 the typical range of equipment features.

280 The architecture separates the interfaces to the various function-specific services from their
281 implementations. A specific implementation architecture might choose to make this a deployment
282 separation, as shown in Figure 4, or might choose to bundle them within a library implementation.

283

284

Figure 4 Telephony Processing

285 **3.4.1 Circuit-Switched (Voice) Communication Service**

286 The Circuit-Switched Communication (CS) service provides application programs with abstract
287 APIs for dialing, call disconnection, rejecting incoming calls, etc., for voice and video
288 communications. This API is available as [CS].

289 3.4.2 Packet-Switched (Data) Communication Service

290 The Packet-Switched Communication (PS) service provides abstract APIs for initiating and
291 terminating sessions and connections, rejecting incoming calls, etc., for data communications.
292 This API is available as [PS].

293 3.4.3 SMS Communication Service

294 The SMS Communication service provides abstract APIs for sending and receiving SMS
295 messages, receiving notification of events, and checking the status of the SMS service, etc.

296 3.4.4 Equipment Service

297 The Equipment service provides APIs for setting up, controlling, and reading the status of various
298 handset hardware elements (batteries, headsets, etc.).

299 3.4.5 Personal Information Manager Service

300 PIM provides abstract APIs for registering a schedule (calendar) item, sorting the schedule,
301 reading to-do data, etc.

302 3.4.6 Data Exchange Service

303 The Data Exchange service provides abstract APIs for handling phone-book, memo, image, and
304 video content, etc. on internal and removable memory stores.

305 3.4.7 Record and Playback Service

306 Record and Playback provides application programs with record and playback of voice memo.

307 3.4.8 Light Management Service

308 The Light Management service provides APIs for programs to for control various lights.

309 3.4.9 Sound Service

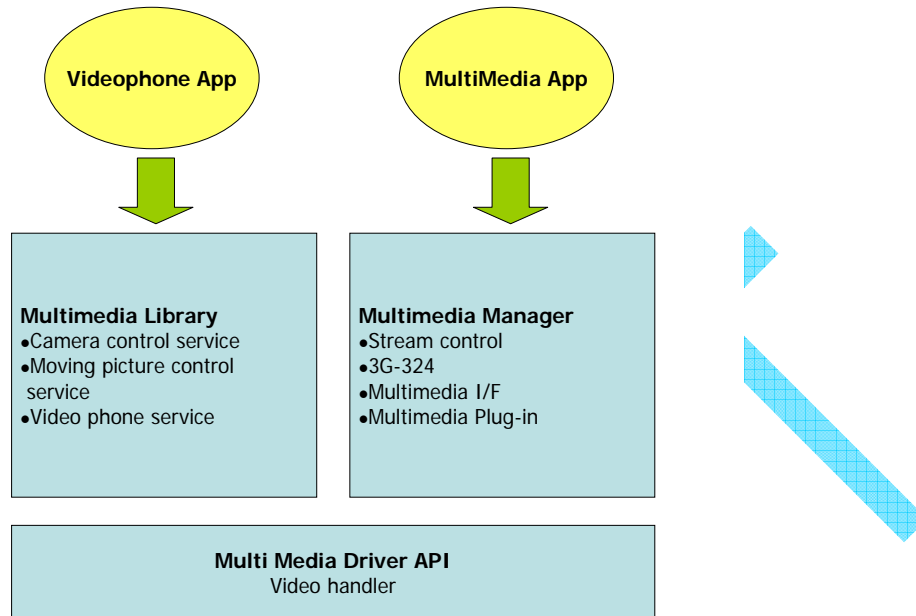

310 The Sound service provides abstract APIs for functions to play and manage ring-tones and other
311 sounds.

312 3.4.10 User Profile Library

313 The User Profile library provides application programs with the ability to read and set various
314 attributes of the user's profile, such as registered phone numbers and owner name

315 **3.5 Multimedia Service**

316 Figure 5 describes the multimedia service.

317

318

Figure 5 Multimedia Framework

319 **3.5.1 Multimedia Manager**

320 The Multimedia Manager provides interfaces for interconnecting multimedia functions, such as
321 video phone library, 3G-H324M protocol support, camera control library, and moving picture
322 control library.

323 **3.5.2 Multimedia Library**

324 The Multimedia Library provides interfaces for camera control, moving picture control, and video
325 phone services.

326 **3.5.3 Multimedia Driver API**

327 Multimedia Driver API provides video handler interfaces.

328 **3.6 Feature Services**

329 This block covers various kinds of add-on functionality related to product-specific features, such
330 as special-purpose hardware, location-awareness, etc.

331 **3.7 Connectivity Service**

332 The OBEX (object exchange) module supports synchronization and sharing of information
333 between devices by exchange of data objects. It provides an interface that is used by OBEX to
334 perform communication processing based on request messages from application programs and
335 to return processing results to the application programs. It also provides an interface that is used
336 by OBEX to convert objects to canonical format for interchange.

337 **3.8 Platform Management Service**

338 The Platform Management monitors the activation of each task at the time of power on and the
339 deactivation of each task at the time of power off, as well as the charging and other statuses of
340 the mobile terminal.

341 **3.9 Terminal Adaptation Function (TAF)**

342 The TAF is the interface between the phone software's networking functionality (voice and data)
343 and the network protocols that are used over the connected network(s); it is the entity that
344 actually constructs sessions and connections in response to abstract requests from clients,
345 adapting a generic view of connections to the specific interactions needed for a particular
346 network.

347 Applications do not use the TAF API directly; they use it only through the APIs provided by the
348 Telephony Service.

349 **3.10 Driver API**

350 The Driver API provides upper layer components (middleware and application programs) present
351 an abstract interface to device drivers, so that device-independent components do not need to be
352 aware of the particular device drivers available on a specific handset, hardware-specific ioctls,
353 etc. This avoids hardware dependencies, enabling development of portable middleware and
354 application programs for mobile phones. The Driver API sits between the client applications and
355 the actual device drivers.

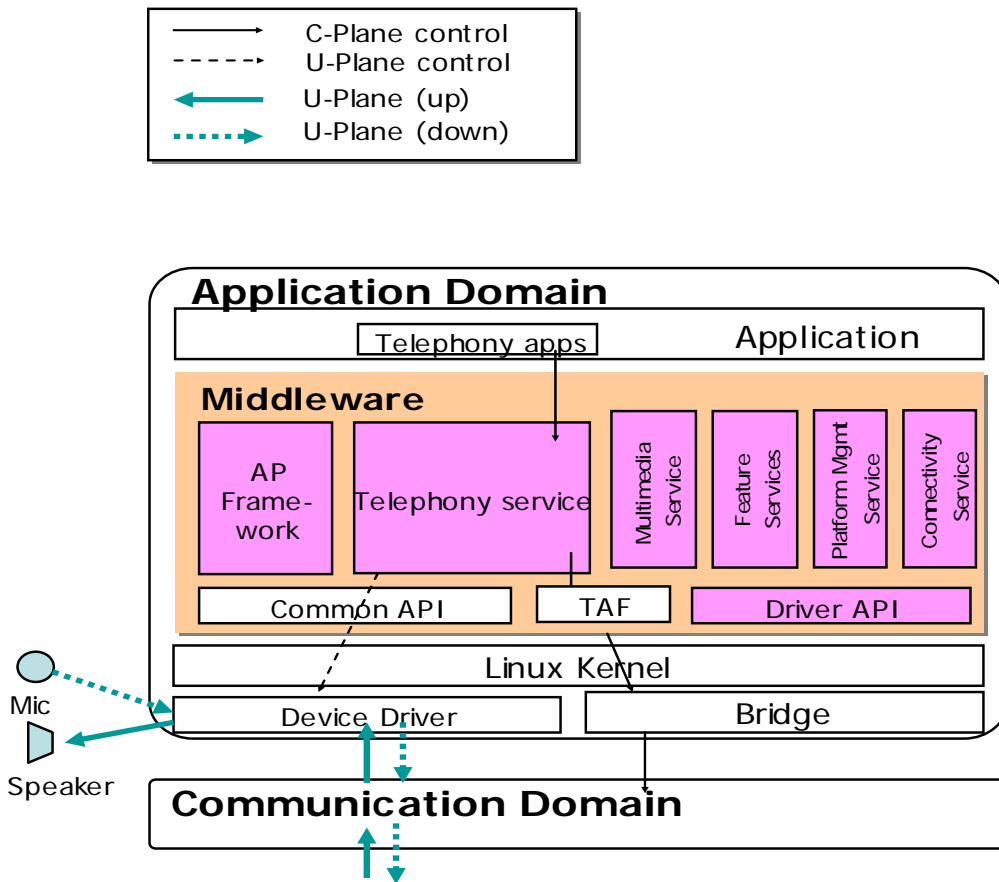

356 **4. Data Flows**

357 This section describes data and control flow between components of the architecture in various
 358 domains.

359 **4.1 Voice communication**

360 Telephony application controls the C-plane using the telephony service. This figure shows the
 361 flows for a mobile-originated call; for a mobile-terminated call there would also be C-plane flows
 362 upward into the telephony service to announce the incoming call.

363 Incoming voice data is decoded by a protocol-specific codec and sent to the appropriate audio
 364 output; the user's voice is encoded and sent to the network.

365
 366
 367

Figure 6 Voice Communication

368

4.2 Video phone

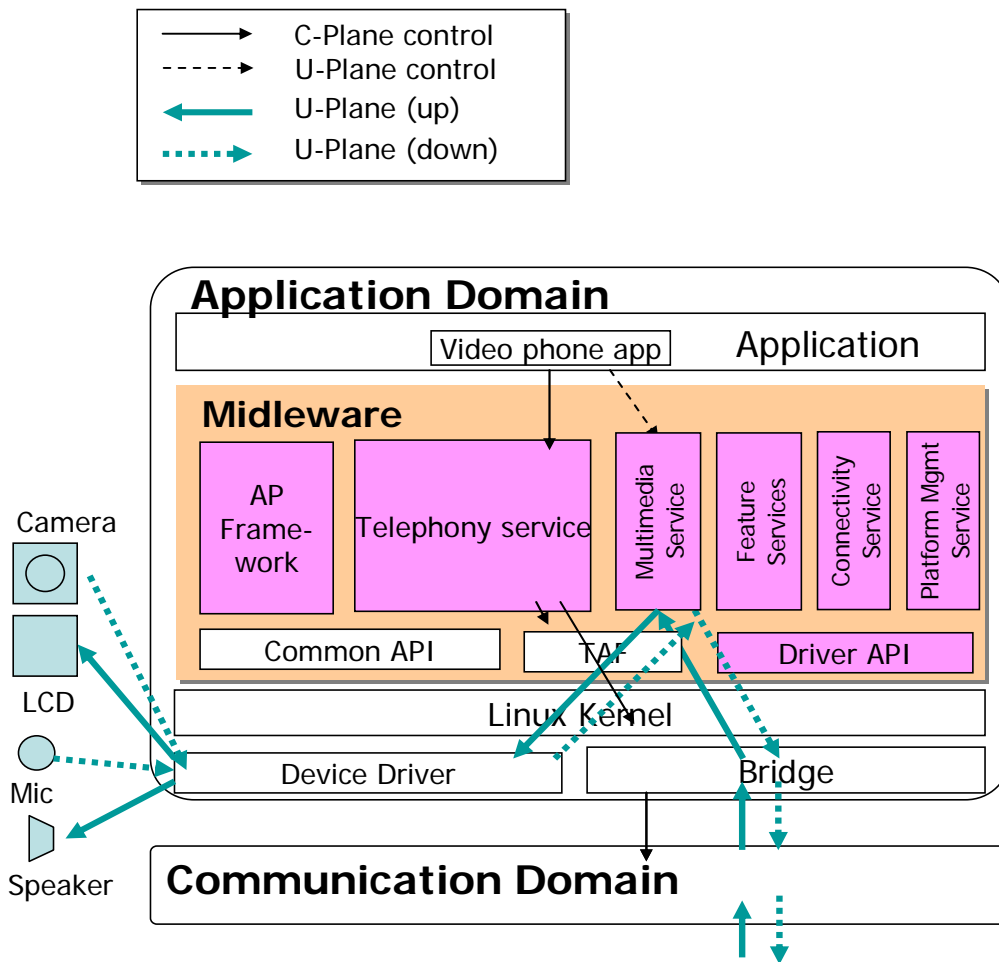

369

Video phone application program controls C-Plane by telephony service.

370

Multimedia service provides decoding and encoding facilities to support video telephony, such as H.324.

371

372

373

374

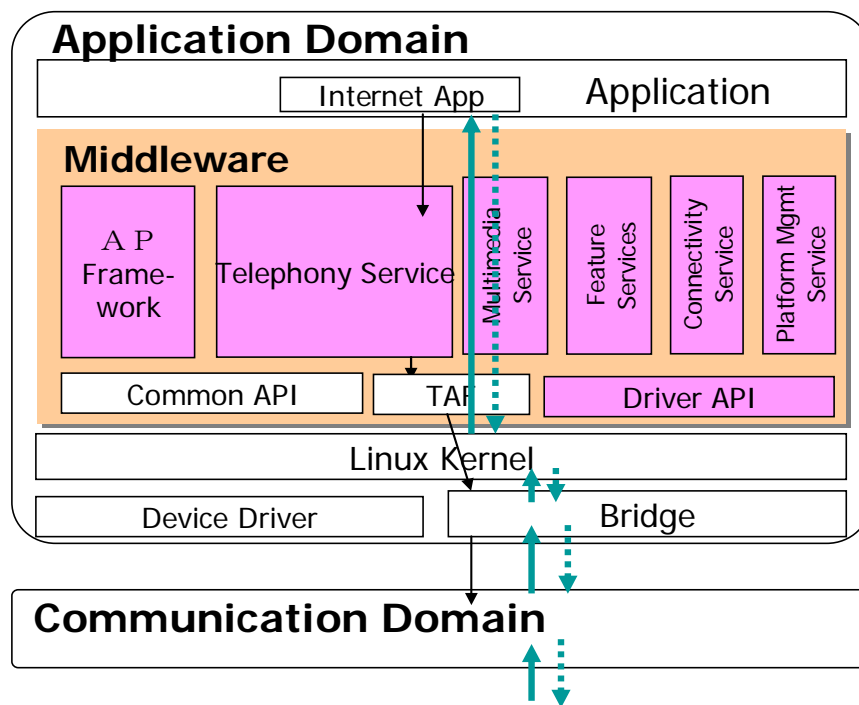

Figure 7 Video Phone

375 **4.3 Internet Application**

376 Internet Application program controls C-Plane by telephony service.

377 Data from the Internet is transported by a protocol stacked based on TCP/IP using the Linux
 378 Kernel networking capabilities.

379
 380
 381

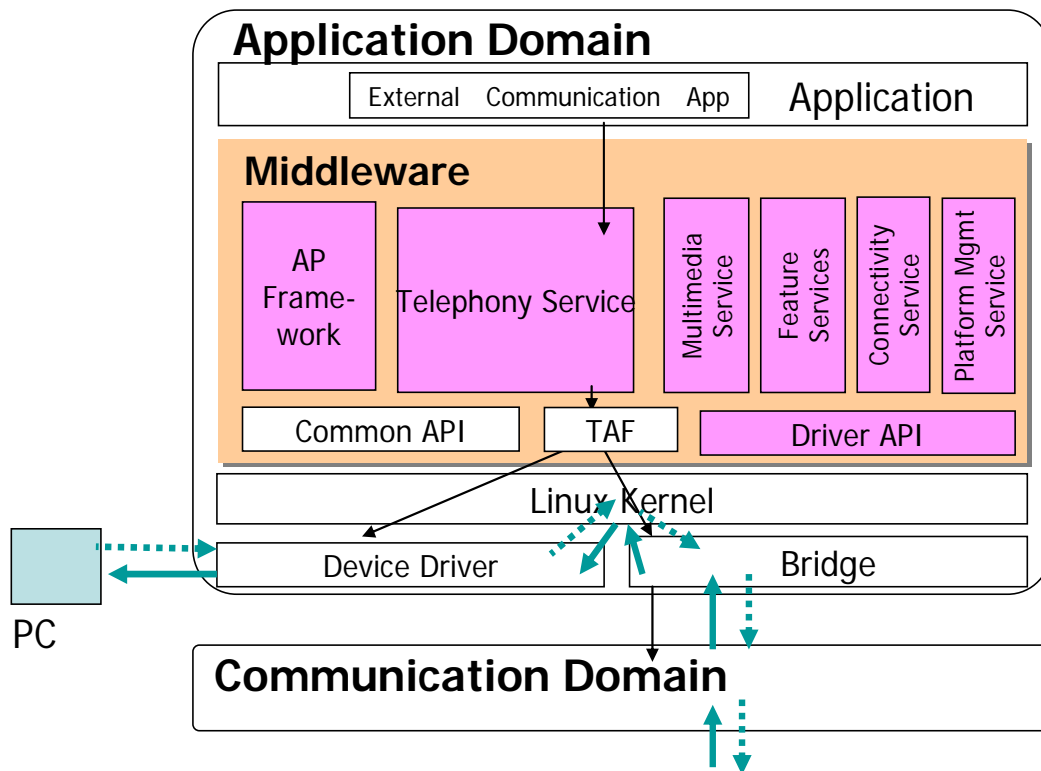

Figure 8 Internet Application

382 4.4 Dial-up Networking with External Devices

383 Applications program for dial-up networking controls C-Plane by telephony service.

384 Data are received and transmitted to an attached external device through USB or other
 385 communication bus and device driver and routed back to the internet through the communications
 386 stack.

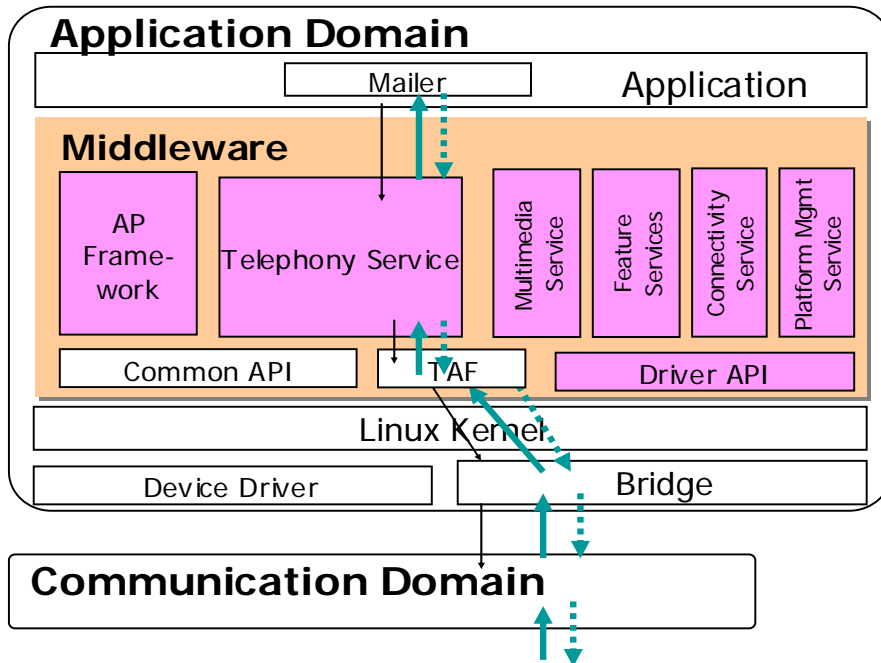

387
 388
