Swapping and embedded: compression relieves the pressure?

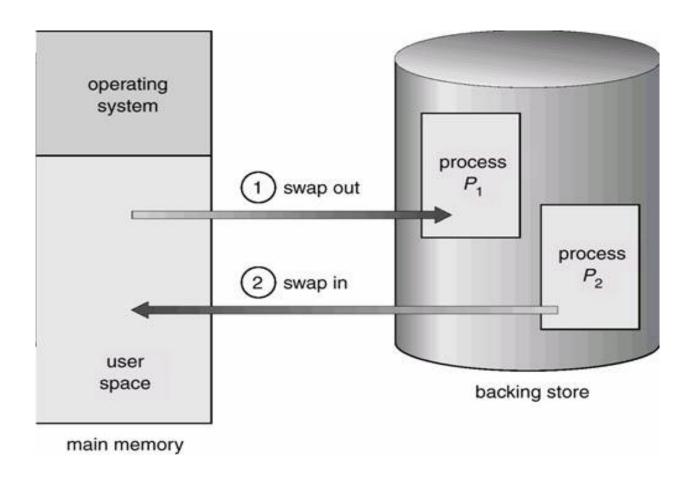

Vitaly Wool

Embedded Linux Conference 2016

Swapping (Paging)

- Paging: [OS capability of] using a secondary storage to store and retrieve data
 - With RAM being primary
 - Storing and retrieving happens on a per-page basis
- Page
 - Uni-size storage block, usually of size 2ⁿ
 - Corresponds to a single record in page table
- Paging is only possible with VM enabled

Swapping

Embedded device objectives

- [very] limited RAM
- [relatively] slow storage
 - Using swap will hurt performance
- [relatively] small storage
 - Hardly is there a place for big swap
- Flash chip used as a storage
 - Swap on flash wears it out fast

Swapping in Embedded

- Should be applicable
 - Constrained RAM
- But is isn't sometimes
 - Constrained storage
- May have adverse effects
 - Flash storage faster wear-out
 - Longer delays if the storage device is slow
- There has to be a way out...

Swapping optimization: zswap

- zswap: compressed write-back cache for swapped pages
 - Write operation completion signaled on write-tocache completion
- Compresses swapped-out pages and moves them into a pool
 - This pool is dynamically allocated in RAM
- Configurable parameters
 - Pool size
 - Compression algorithm

zswap backend: zbud

- zbud: special purpose memory allocator
 - allocation is always per-page
- Stores up to 2 compressed pages per page
 - One bound to the beginning, one to the end
 - The in-page pages are called "buddies"
- Key characteristics
 - Simplicity and stability
- zbud is the allocator backend for zswap

RAM as a swap storage

- Compression required
 - No gain otherwise
 - But increases CPU load
- Implementation of a [virtual] block device required
- Careful memory management is required
 - Should not use high-order page allocations

ZRAM

- Block device for compressed data storage in RAM
 - Compression algorithm is configurable
 - Default algorithm is LZO
 - LZ4 is used mostly
- Usually deployed as a self-contained swap device
 - The size is specified in runtime (via sysfs)
 - Configuration is the same otherwise

ZRAM vs Flash swap

- Compared on Carambola (MIPS24kc)
 - Details on the configuration will follow
- Standard I/O measurement tools
 - 'fio' with 'tiobench' script
- Results
 - Average read speed: 730 vs 699 (kb/s)
 - Average write speed: 180.5 vs 172 (kb/s)
- Difference is larger where RAM is faster

zsmalloc: ZRAM backend

- Special purpose pool-based memory allocator
- Packs objects into a set of noncontiguous pages
 - ZRAM calls into zsmalloc to allocate space for compressed data
 - Compressed data is stored in scattered pages within the pool

z--- in detail>

zsmalloc and zbud compared

	zsmalloc	zbud
Compression ratio	High (3x – 4x)	Medium/Low (1.8x – 2x)
CPU utilization	Medium/High	Medium
Internal fragmentation	yes	no
Latencies	Medium/Low	Low

z--- in detail>

zpool: a unified API

- Common API for compressed memory storage
- Any memory allocator can implement zpool API
 - And register in zpool
- 2 main zpool users
 - zbud
 - zsmalloc

z--- in detail>

zswap uses zpool API!

- zswap is now backend-independent
 - As long as the backend implements zpool API
- zswap can use zsmalloc
 - Better compression ratio
 - Less disk/flash utilization

ZRAM moving forward>

What if ZRAM used zbud?

- Persistent storage is not used anyway
 - Compression ratio may not be the key
- No performance degrade over time
- Less dependency on memory subsystem
- CPU utilization may get lower
- Throughput may get higher
- Latencies may get lower

ZRAM moving forward>

Why can't ZRAM use zbud?

- zbud can't handle PAGE_SIZE allocations
 - Uses small part of the page for internal structure
 - Called struct zbud_header
 - Easy to fix: it can go to struct page
- ZRAM doesn't use zpool API
 - zsmalloc API fits zpool API nicely
 - Easy to fix: just implement it

ZRAM moving forward>

Allow ZRAM to use zbud

- An initiative taken by the author
 - Allow PAGE_SIZE allocations in ZBUD
 - Make ZRAM use zpool
- Two mainlining attempts
 - https://lkml.org/lkml/2015/9/14/356 [1]
 - https://lkml.org/lkml/2015/9/22/220 [2]
 - Faced strong opposition from ZRAM authors
 - Vendor neutrality questionable
- More attempts to come

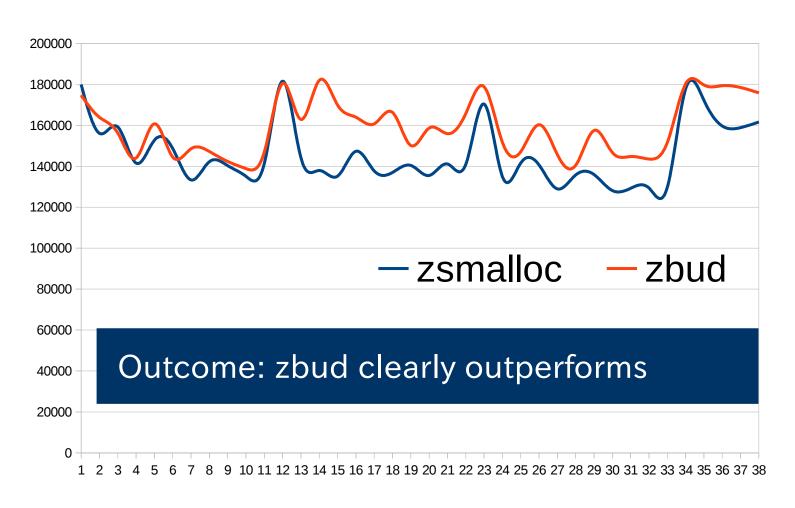

Prerequisites

- Use fio for performance measurement
 - Written by Jens Axboe
 - Flexible and versatile
- EXT4 file system on /dev/zram0
 - 50% full
- A flavor of fio 'enospc' script
 - Adapted for smaller block device (zram)
- 40 iterations per z--- backend (zbud/zsmalloc)

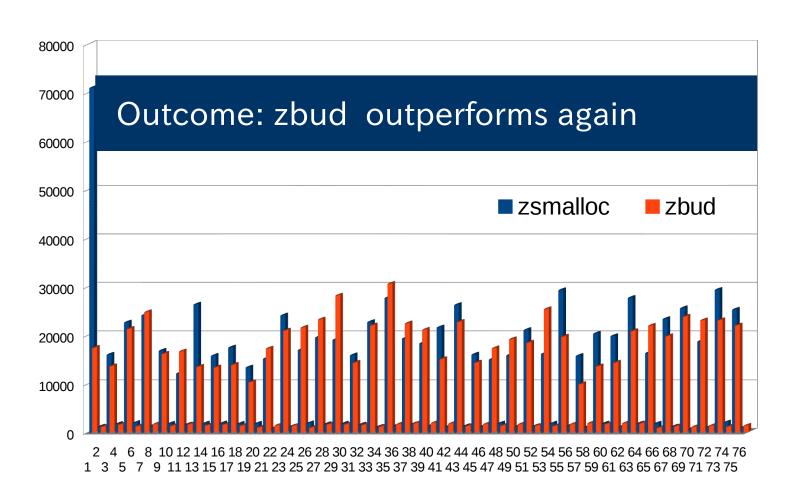

Test device 1

- Sony Xperia Z2
 - MSM8974 CPU
 - 2.3 GHz Quad-Core Krait™
 - 3 GB RAM
- Cyanogenmod build as of Jan 15, 2016 (12.1)
 - A flavor of Android 5.1.1
 - Custom 3.10-based kernel

ZRAM performance: Android

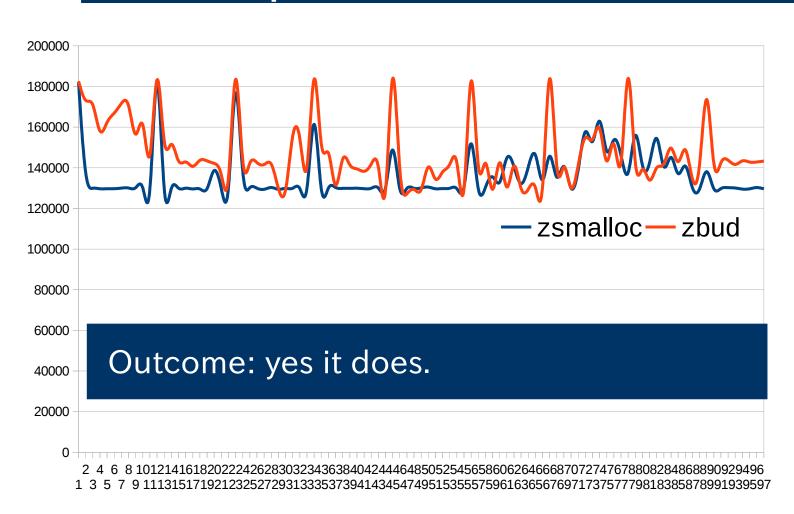

ZRAM latency: Android

ZRAM performance: Android

Okay what happens in the long run, does zbud remain superior to zsmalloc?

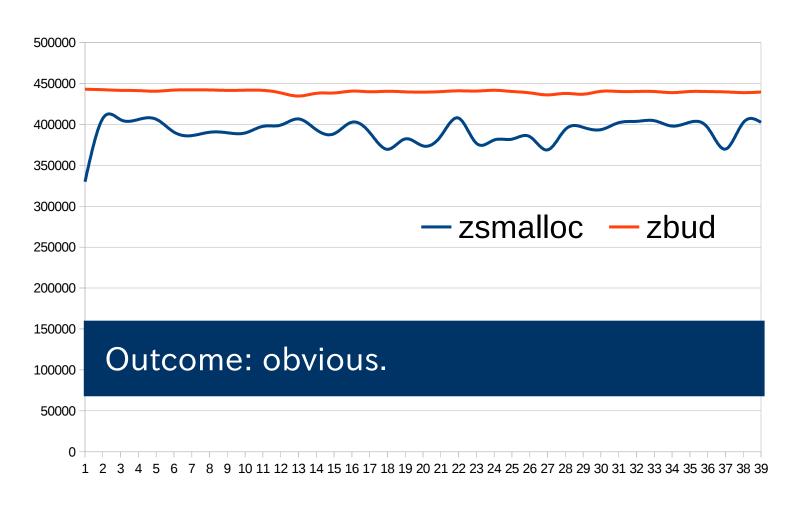

ZRAM performance: Android

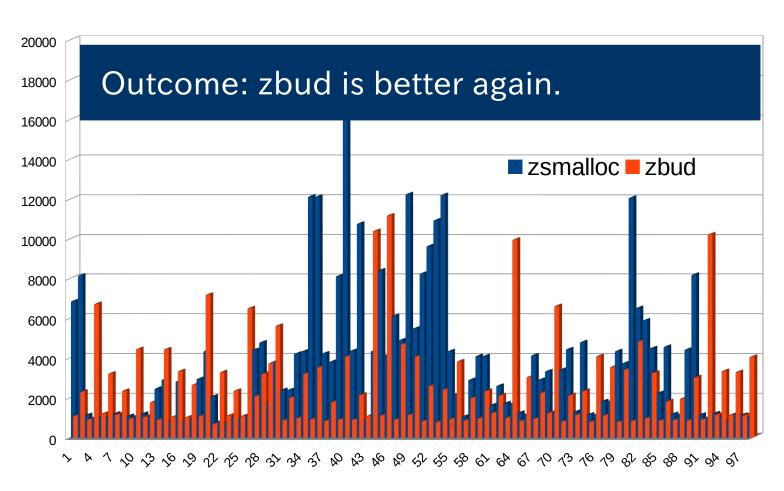

Test device 2

- Intel Minnowboard Max EVB
 - 64bit Atom™ CPU E3815 @ 1.46GHz
 - DDR3 2 GB RAM
 - Storage 4 GB eMMC
- Debian 8.4 64 bit
 - Custom 4.3-based kernel

ZRAM performance: x86_64

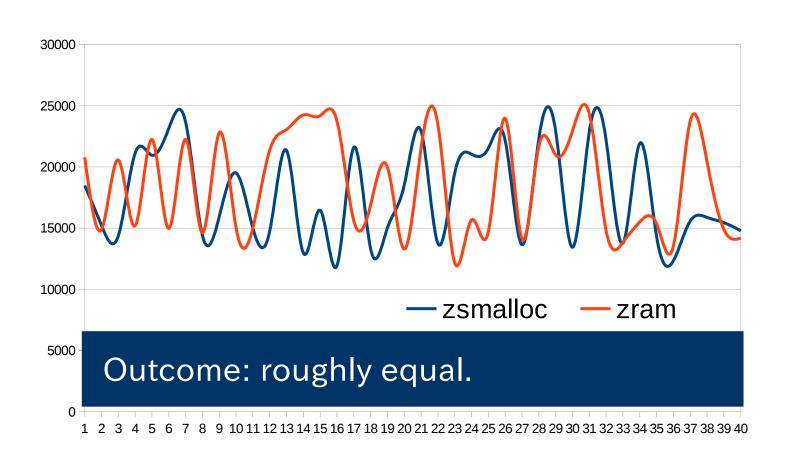

ZRAM latency: x86_64

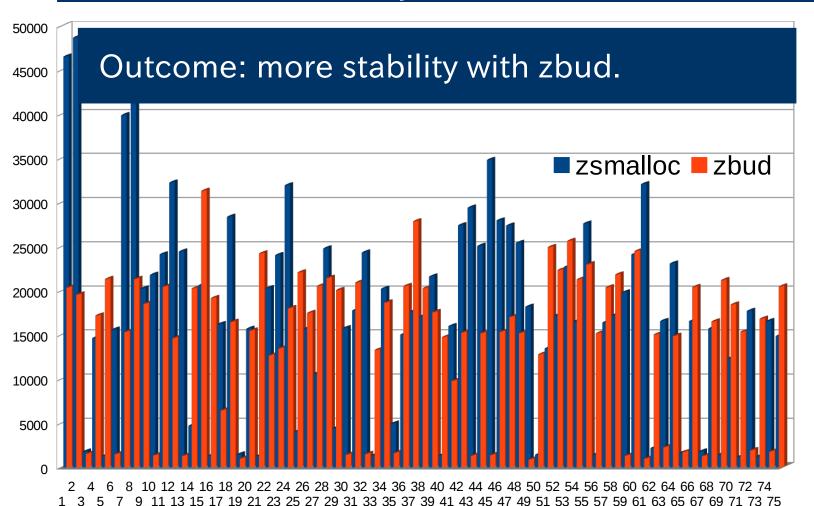

Test device 3

- Carambola 2
 - MIPS32 24Ke
 - Qualcomm/Atheros AR9331 SoC
 - 400 MHz CPU
 - 64 MB DDR2 RAM
 - Storage 512 MB NAND flash
- OpenWRT
 - Git as of Jan 15, 2016
 - Custom 4.3-based kernel

ZRAM performance: MIPS32

ZRAM latency: MIPS32

Wrap-Up

- Compressed RAM swap is a generous idea
 - Many systems can benefit from it
- Two implementations mainlined
 - Zswap: mostly targeting big systems
 - ZRAM: mostly for embedded / small systems
- Each has its own backend
 - Zswap uses zbud
 - ZRAM uses zsmalloc

Conclusions

- Compressed RAM swap is the way out for embedded systems
- ZRAM over zbud is a good match for non-compression-ratio-demanding cases
 - Lower latencies
 - Higher throughput
 - Minimal aging
- Having options is good

swapping completed.
